Computer Structures

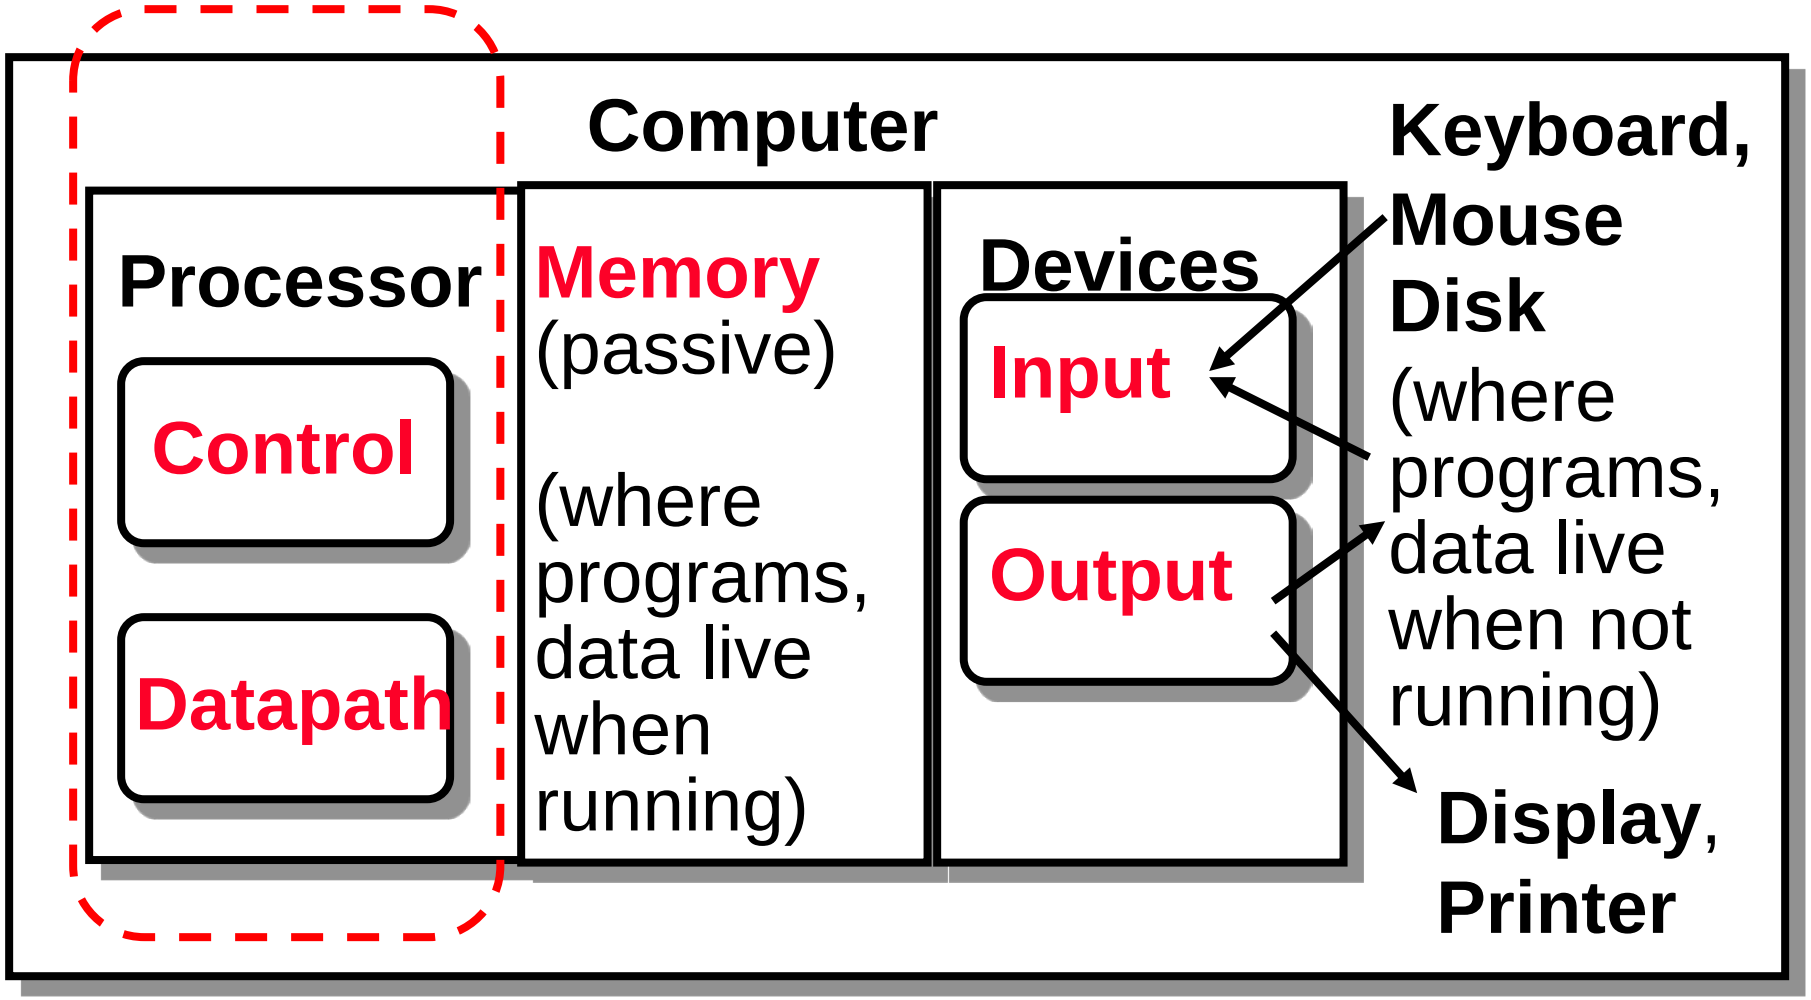
Introduction to CPU Design

Dr. Liqiang Zhang

Department of Computer and Information Sciences

Adapted from Morgan Kaufmann and others

Five Components of a Computer



The CPU

- Processor (CPU): the active part of the computer, which does all the work (data manipulation and decision-making)
- Datapath: portion of the processor which contains hardware necessary to perform operations required by the processor (the brawn)
- Control: portion of the processor (also in hardware) which tells the datapath what needs to be done (the brain)

Stages of the Datapath : Overview

- Problem: a single, atomic block which “executes an instruction” (performs all necessary operations beginning with fetching the instruction) would be too bulky and inefficient
- Solution: break up the process of “executing an instruction” into stages, and then connect the stages to create the whole datapath
  - smaller stages are easier to design
  - easy to optimize (change) one stage without touching the others

Stages of the Datapath (1/5)

- There is a *wide* variety of MIPS instructions: so what general steps do they have in common?
- Stage 1: Instruction Fetch
  - no matter what the instruction is, the 32-bit instruction word must first be fetched from memory (the cache-memory hierarchy)
  - also, this is where we Increment PC
    (that is, PC = PC + 4, to point to the next instruction: byte addressing so + 4)

Stages of the Datapath (2/5)

- Stage 2: Instruction Decode
  - upon fetching the instruction, we next gather data from the fields (*decode* all necessary instruction data)
  - first, read the Opcode and Funct to determine instruction type and field lengths
  - second, read in data from all necessary registers
    - for `add`, read
    - for `addi`, read
    - for `jal`, read

Stages of the Datapath (3/5)

- Stage 3: ALU (Arithmetic-Logic Unit)
  - the real work of most instructions is done here: arithmetic (+, -, *, /), shifting, logic (&, |), comparisons (`slt`)
  - what about loads and stores?
    - `lw  $t0, 40($t1)`
    - the address we are accessing in memory = the value in `$t1` PLUS the value 40
    - so we do this addition in this stage

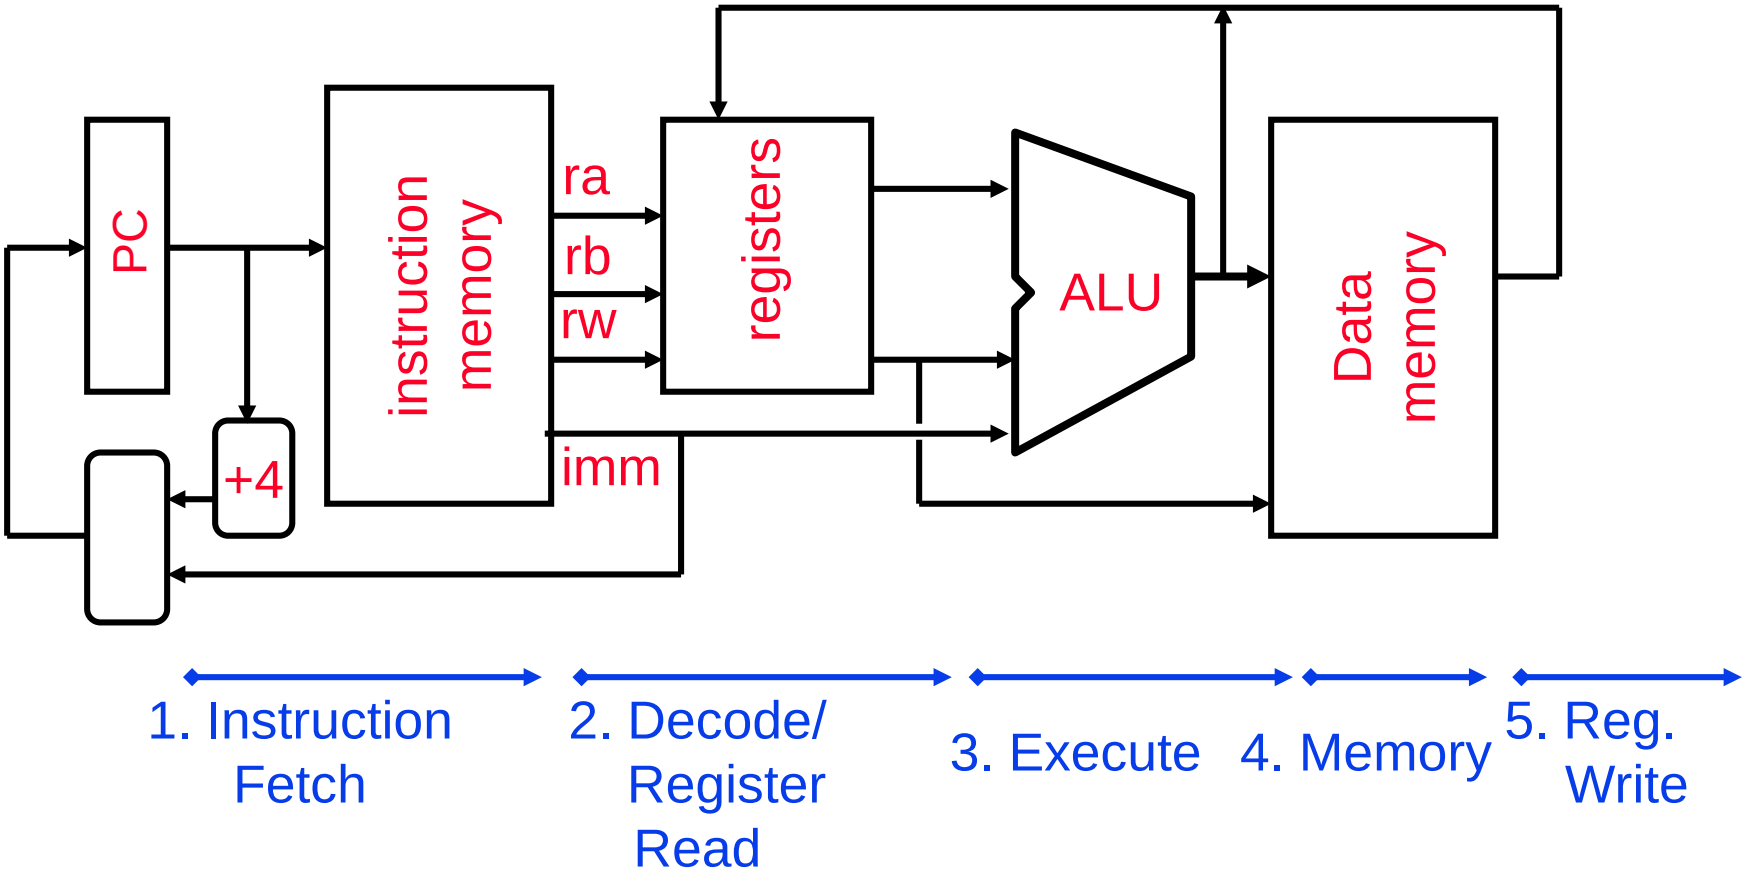
Stages of the Datapath (4/5)

- Stage 4: Memory Access
  - actually only the load and store instructions do anything during this stage; the others remain idle during this stage or skip it all together
  - since these instructions have a unique step, we need this extra stage to account for them
  - as a result of the cache system, this stage is expected to be *fast*

Stages of the Datapath (5/5)

- Stage 5: Register Write
  - most instructions write the result of some computation into a register
  - examples: arithmetic, logical, shifts, loads, `slt`
  - what about stores, branches, jumps?
    - don’t write anything into a register at the end
    - these remain idle during this fifth stage or skip it all together

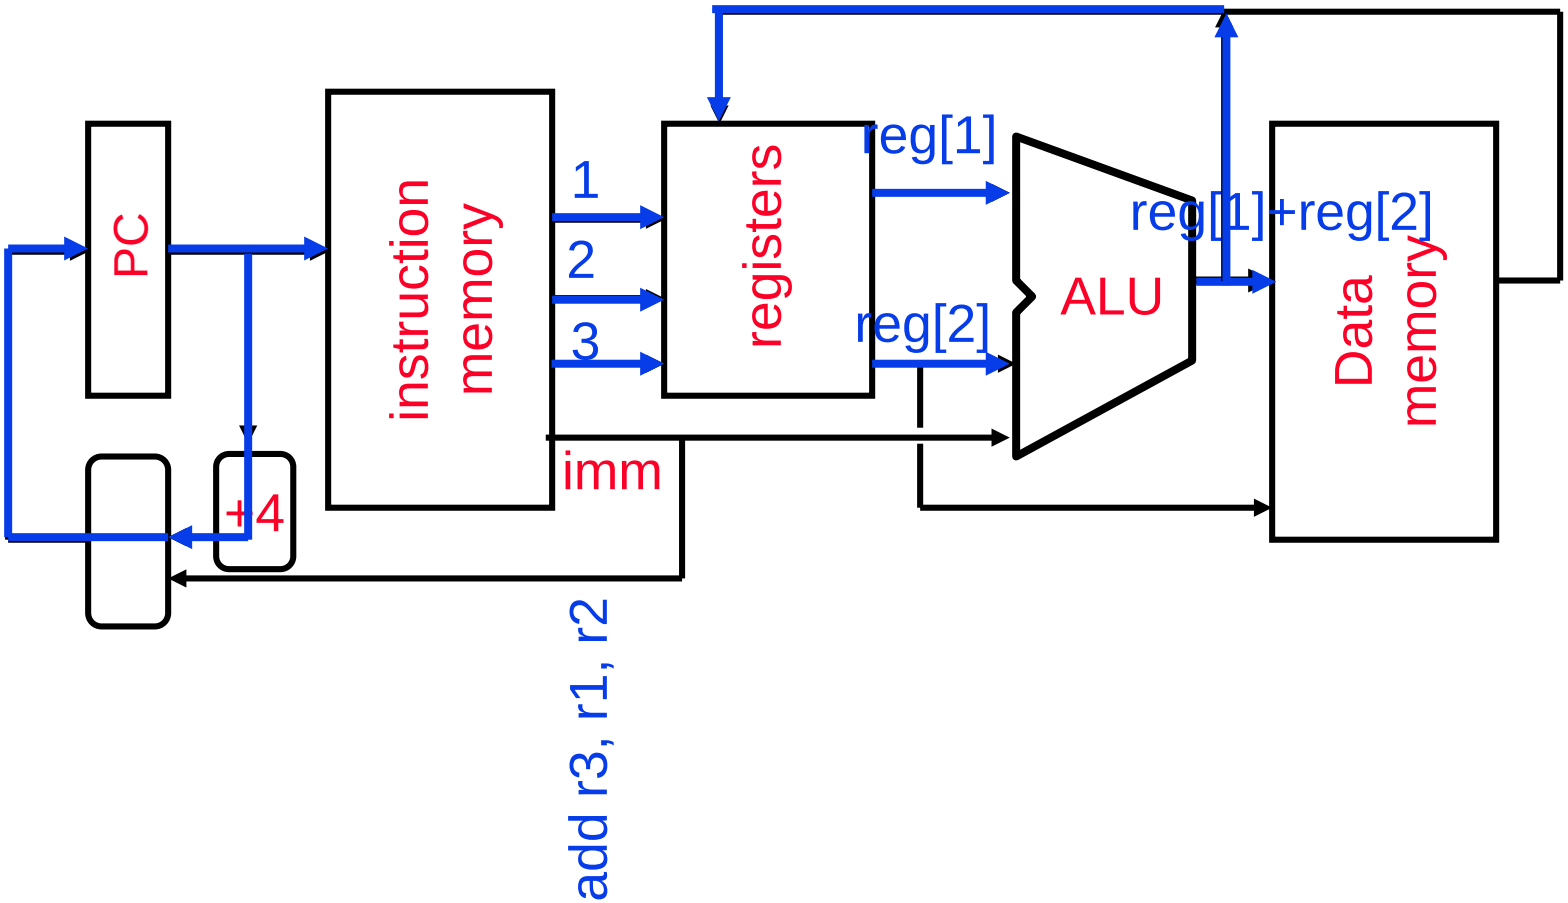
Generic Steps of Datapath



Datapath Walkthroughs (1/3)

- `add $r3,$r1,$r2 # r3 = r1+r2`
  - Stage 1: fetch this instruction, inc. PC
  - Stage 2: decode to find it's an `add`, then read registers `$r1` and `$r2`
  - Stage 3: add the two values retrieved in Stage 2
  - Stage 4: idle (nothing to write to memory)
  - Stage 5: write result of Stage 3 into register `$r3`

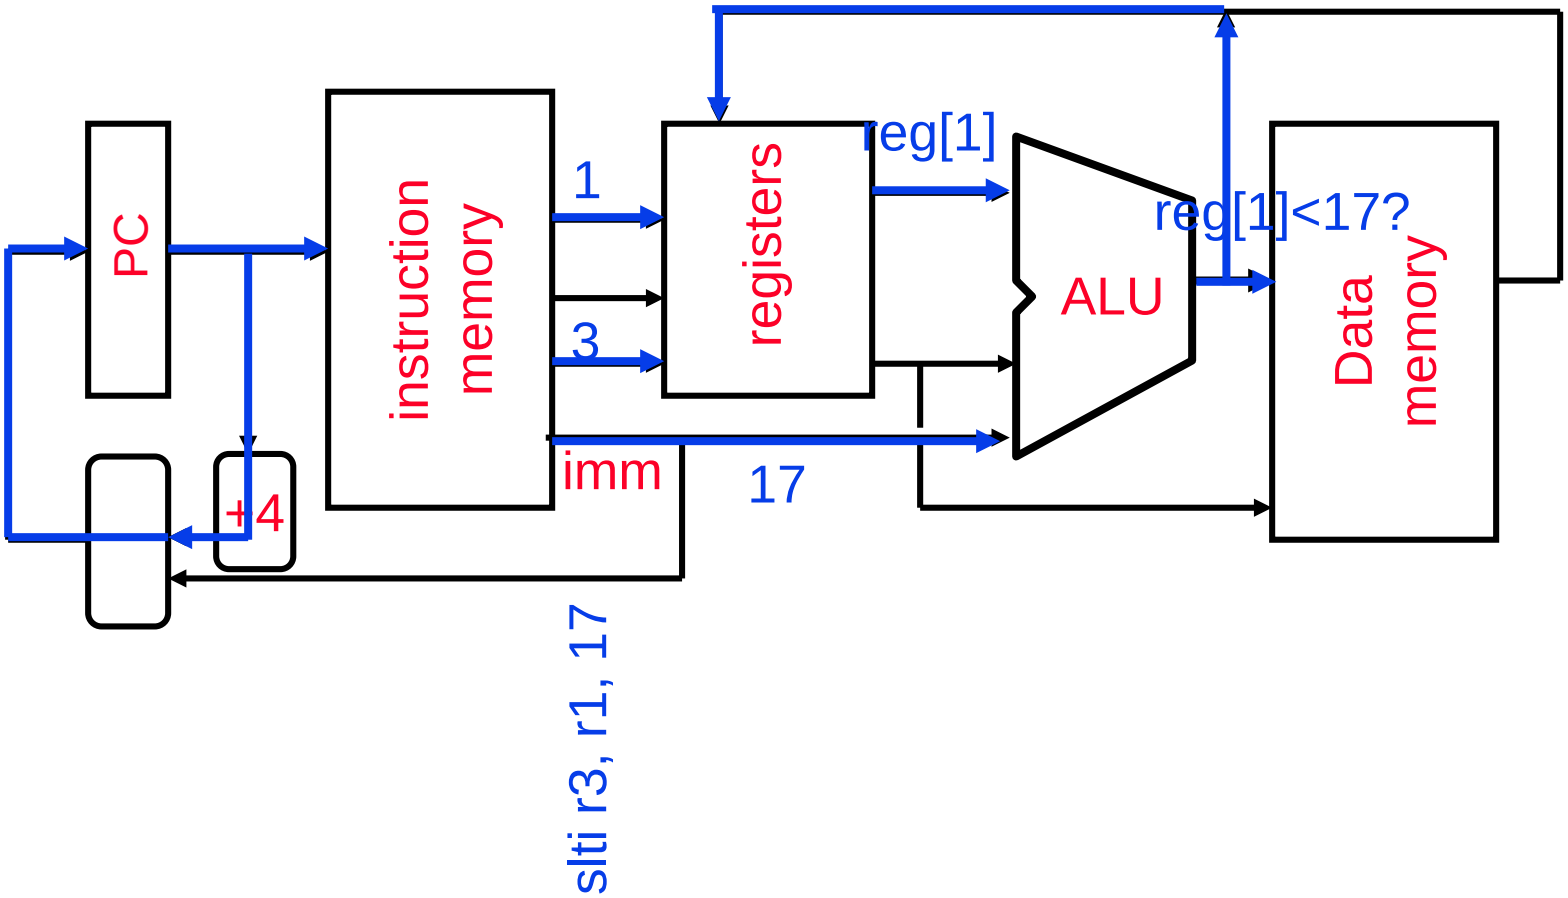
Example: add Instruction



Datapath Walkthroughs (2/3)

- `slti  $r3,$r1,17`
  - Stage 1: fetch this instruction, inc. PC
  - Stage 2: decode to find it's an `slti`, then read register `$r1`
  - Stage 3: compare value retrieved in Stage 2 with the integer 17
  - Stage 4: idle
  - Stage 5: write the result of Stage 3 in register `$r3`

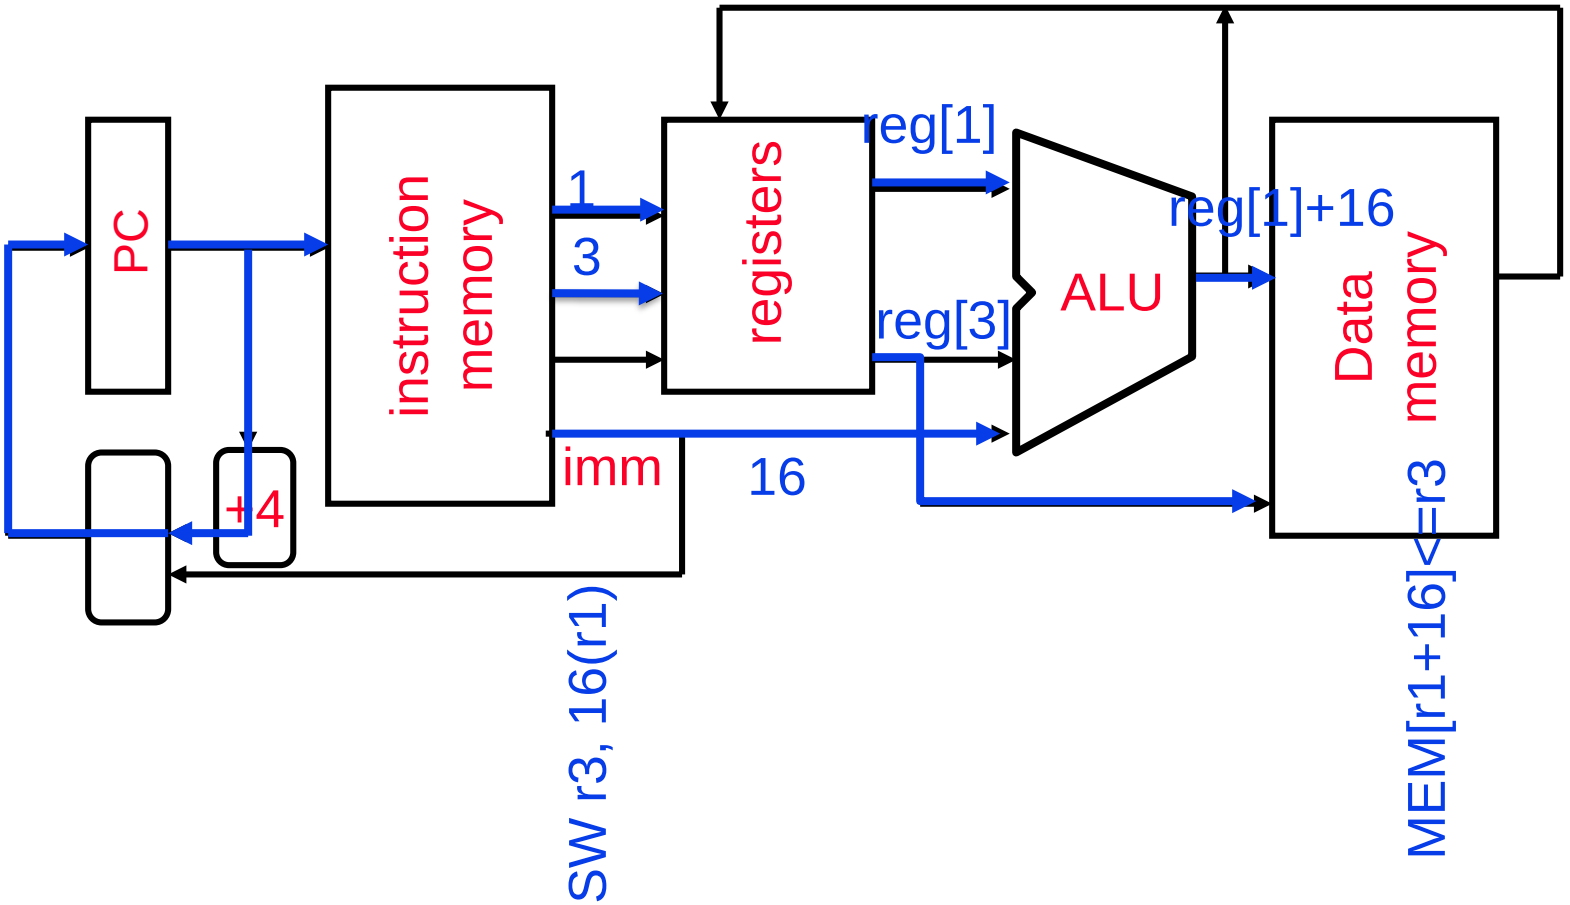
Example: `slti` Instruction



Datapath Walkthroughs (3/3)

- `sw  $r3, 16($r1)`
  - Stage 1: fetch this instruction, inc. PC
  - Stage 2: decode to find it's a sw, then read registers $r1 and $r3
  - Stage 3: add 16 to value in register $1 (retrieved in Stage 2)
  - Stage 4: write value in register $r3 (retrieved in Stage 2) into memory address computed in Stage 3
  - Stage 5: idle (nothing to write into a register)

Example: sw Instruction



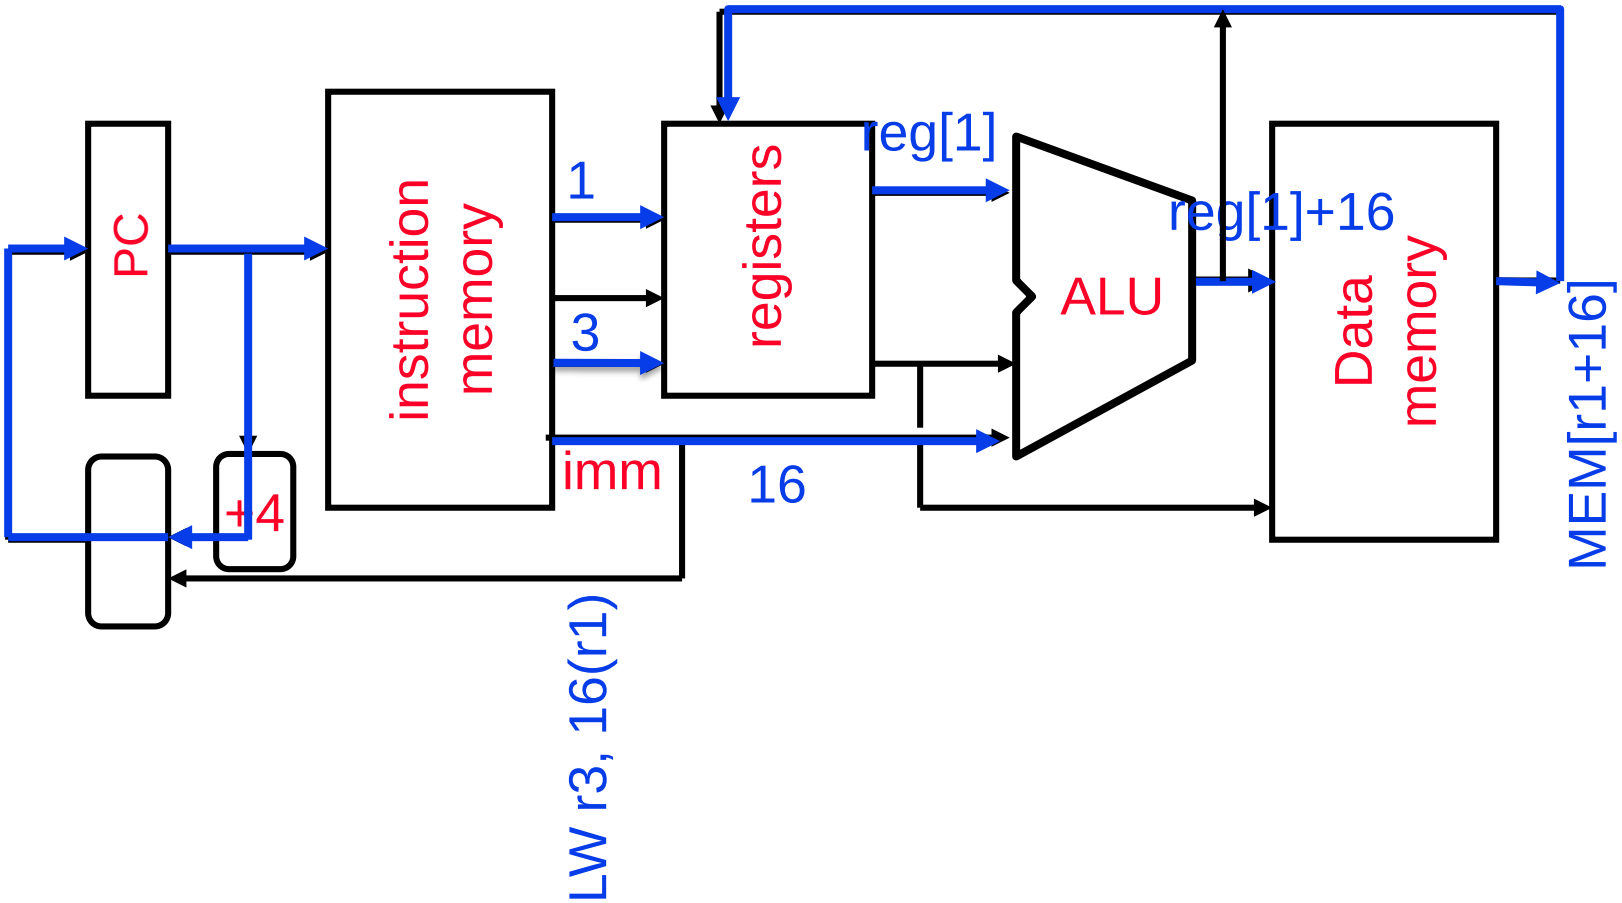
Why Five Stages? (1/2)

- Could we have a different number of stages?
  - Yes, and other architectures do
- So why does MIPS have five if instructions tend to idle for at least one stage?
  - The five stages are the union of all the operations needed by all the instructions of MIPS.
  - There is one instruction that uses all five stages: the load

Why Five Stages? (2/2)

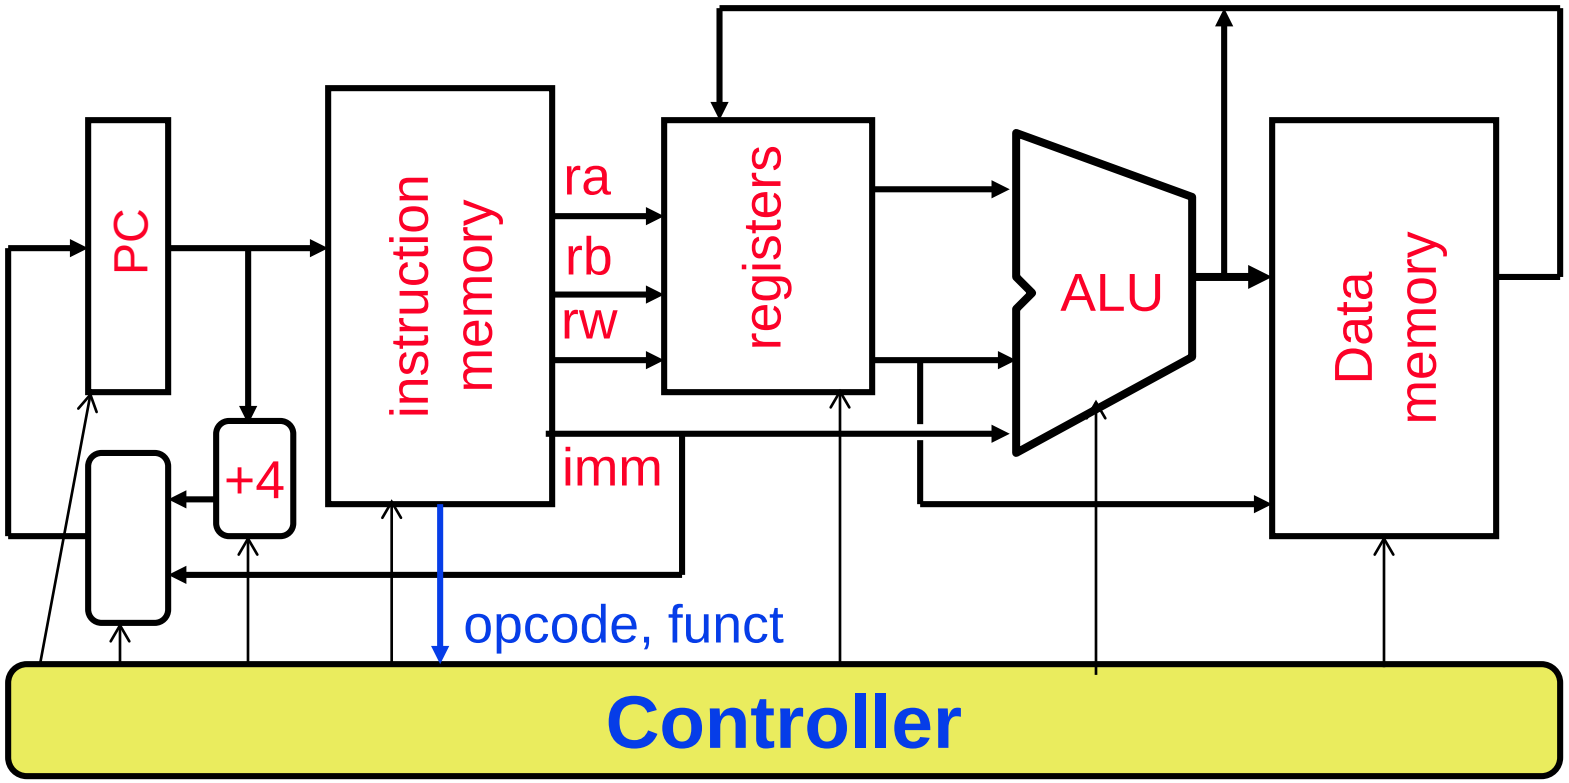
- `lw  $r3, 16($r1)`
  - Stage 1: fetch this instruction, inc. PC
  - Stage 2: decode to find it's a `lw`, then read register `$r1`
  - Stage 3: add 16 to value in register `$r1` (retrieved in Stage 2)
  - Stage 4: read value from memory address compute in Stage 3
  - Stage 5: write value found in Stage 4 into register `$r3`

Example: lw Instruction



Datapath Summary

- The datapath is based on data transfers required to perform instructions
- A *controller* causes the right transfers to happen



What Hardware Is Needed? (1/2)

- PC: a register which keeps track of memory addr of the next instruction
- General Purpose Registers
  - used in Stages 2 (Read) and 5 (Write)
  - MIPS has 32 of these
- Memory
  - used in Stages 1 (Fetch) and 4 (R/W)
  - cache system makes these two stages as fast as possible

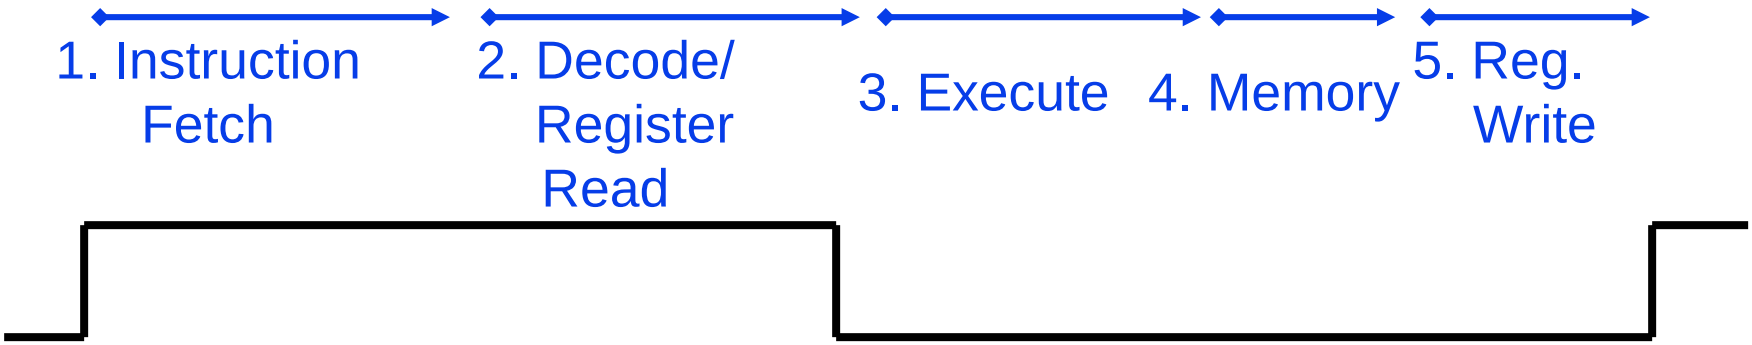
What Hardware Is Needed? (2/2)

- ALU
  - used in Stage 3
  - something that performs all necessary functions: arithmetic, logicals, etc.
- Miscellaneous Registers
  - In implementations with only one stage per clock cycle, registers are inserted between stages to hold intermediate data and control signals as they travels from stage to stage.
  - Note: Register is a general purpose term meaning something that stores bits. Not all registers are in the “register file”.

CPU clocking (1/2)

For each instruction, how do we control the flow of information though the datapath?

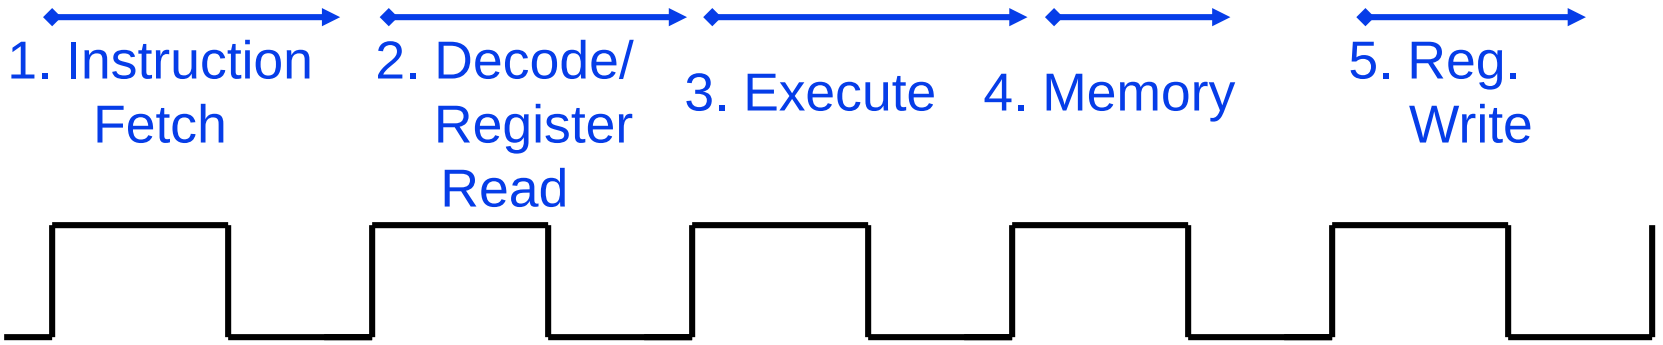
- Single Cycle CPU: All stages of an instruction are completed within one *long* clock cycle.
  - The clock cycle is made sufficient long to allow each instruction to complete all stages without interruption and within one cycle.



CPU clocking (2/2)

For each instruction, how do we control the flow of information though the datapath?

- Multiple-cycle CPU: Only one stage of instruction per clock cycle.
  - The clock is made as long as the slowest stage.



Several significant advantages over single cycle execution:
Unused stages in a particular instruction can be skipped OR instructions can be pipelined (overlapped).

“And In conclusion…”

- CPU design involves Datapath,Control
  - Datapath in MIPS involves 5 CPU stages

1) Instruction Fetch
2) Instruction Decode & Register Read
3) ALU (Execute)
4) Memory
5) Register Write
